Project goals:
1. Investigate cyanobacterial metabolic network and reveal its regulations for fast biosynthesis.
2. Elucidate effects of micro-compartmentation on cyanobacterial metabolisms.

Abstract
Cyanobacterial carboxysomes encapsulate carbonic anhydrase and ribulose-1,5-bisphosphate carboxylase/oxygenase and are key organelles that promote CO₂ concentration and fixation. Genetic deletion of the major structural proteins encoded within the ccm operon in Synechococcus sp. PCC 7002 (ΔccmKLMN) disrupts carboxysome formation and significantly affects cell physiology. In this study, we employed both metabolite pool size analysis and isotopically nonstationary metabolic flux analysis (INST-MFA) to examine metabolic regulation in cells lacking carboxysomes. Under high CO₂ environments, the ΔccmKLMN mutant had similar growth rates as the control strain and maintained a similar flux distribution through the central metabolism, with the exceptions of moderately elevated protein synthesis and photorespiration activity. Metabolite analyses indicated that the ΔccmKLMN strain had larger pool sizes of pyruvate, UDPG, and aspartate as well as higher levels of secreted malate and succinate. Under photomixotrophic conditions, both the control strain and the ΔccmKLMN mutant metabolized acetate and pyruvate. Provision of acetate promoted carboxysome mutant growth when light and CO₂ were insufficient. The results suggest that the ΔccmKLMN mutant is able to minimize changes in fluxes (except for elevated photorespiration) and instead reorganizes its metabolism through significant changes in intracellular metabolite pool concentrations. The removal of microcompartments may loosen the flux network regulation and allow for redirection of central metabolites to competing pathways (e.g., lactate production). This study provides important insights into both metabolic regulation via enzyme compartmentation and the compensatory responses in cyanobacterial phototrophic metabolism.
